Developing Applications for iOS

Fall 2011

Today

- ⦿ **Core Data and Documents**

- This is how you store something serious in iOS
 - Easy entrée into iCloud

- ⦿ **NSNotificationCenter**

- The little “radio station” we talked about in the very first lecture

- ⦿ **Objective-C Categories**

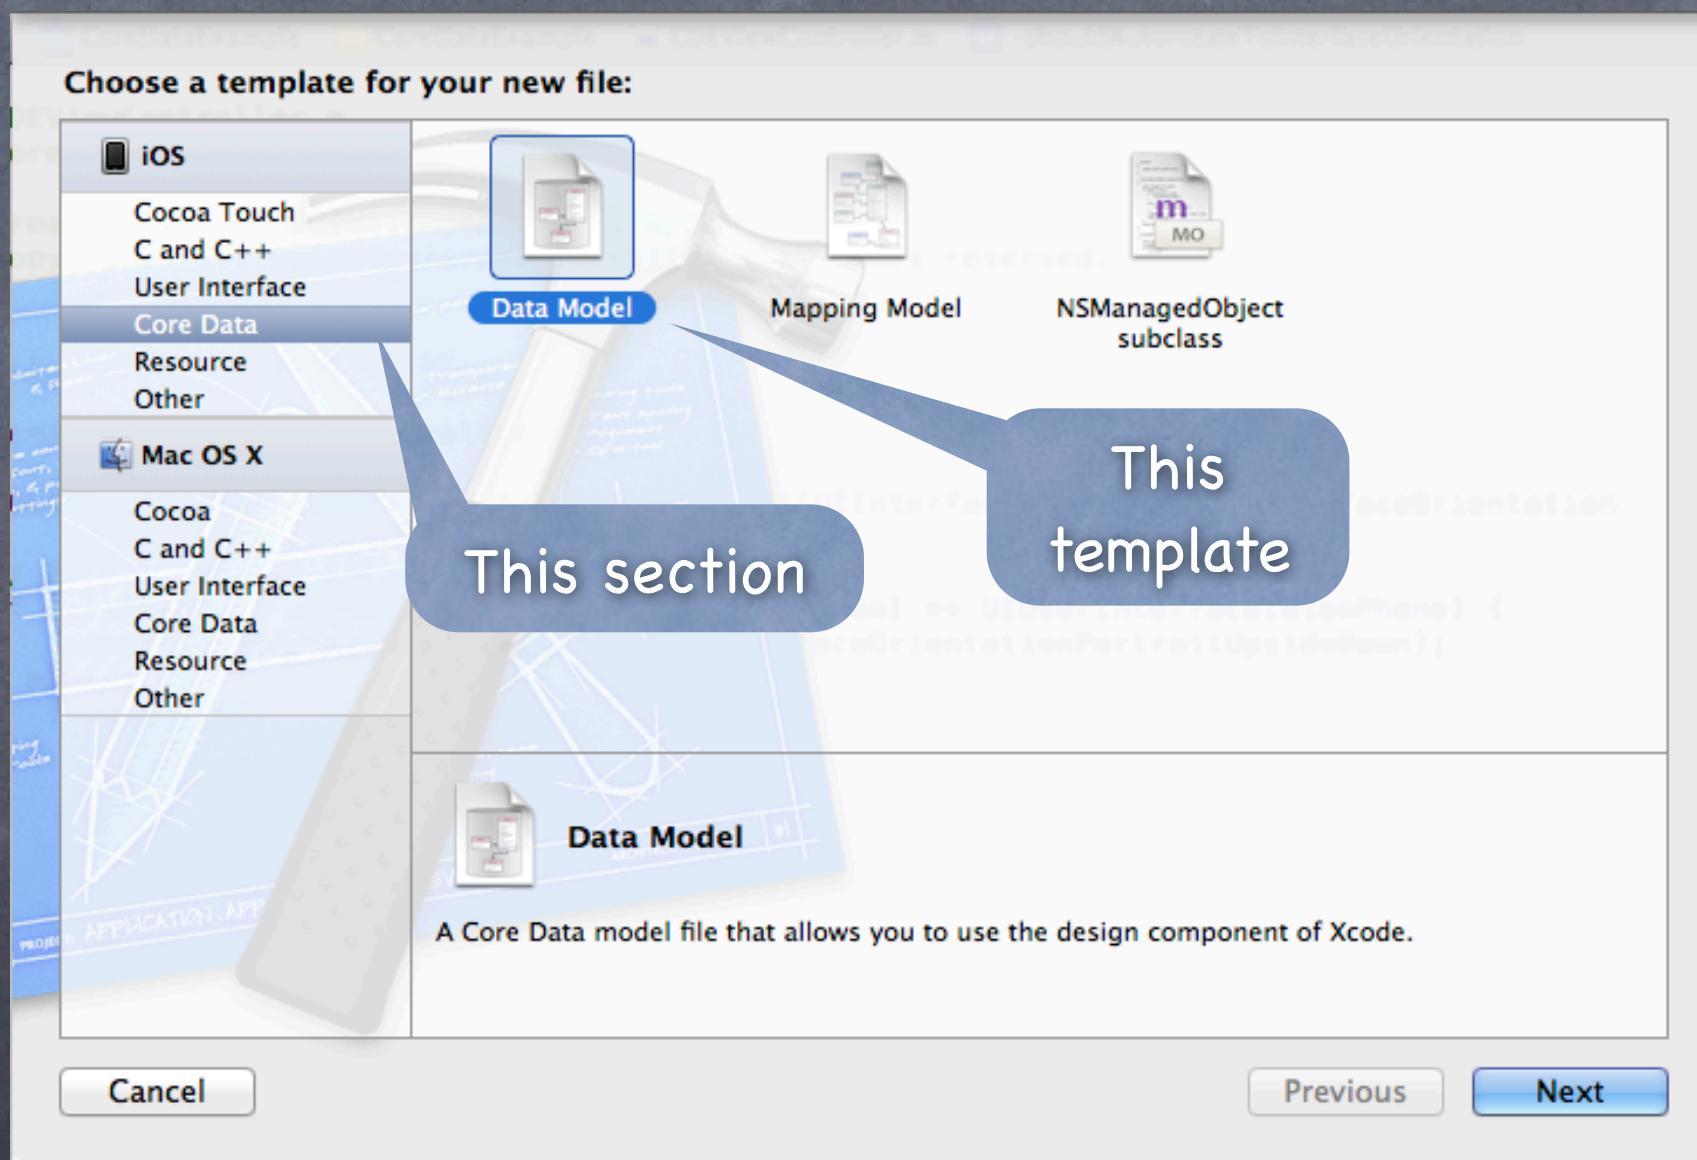

- A way to add methods to a class without subclassing

Core Data

- ⦿ We're object-oriented programmers and we don't like C APIs!
We want to store our data using object-oriented programming!
- ⦿ Enter Core Data
Object-oriented database.
- ⦿ It's a way of creating an object graph backed by a database
Usually SQL.
- ⦿ How does it work?
Create a visual mapping (using Xcode tool) between database and objects.
Create and query for objects using object-oriented API.
Access the "columns in the database table" using @propertys on those objects.

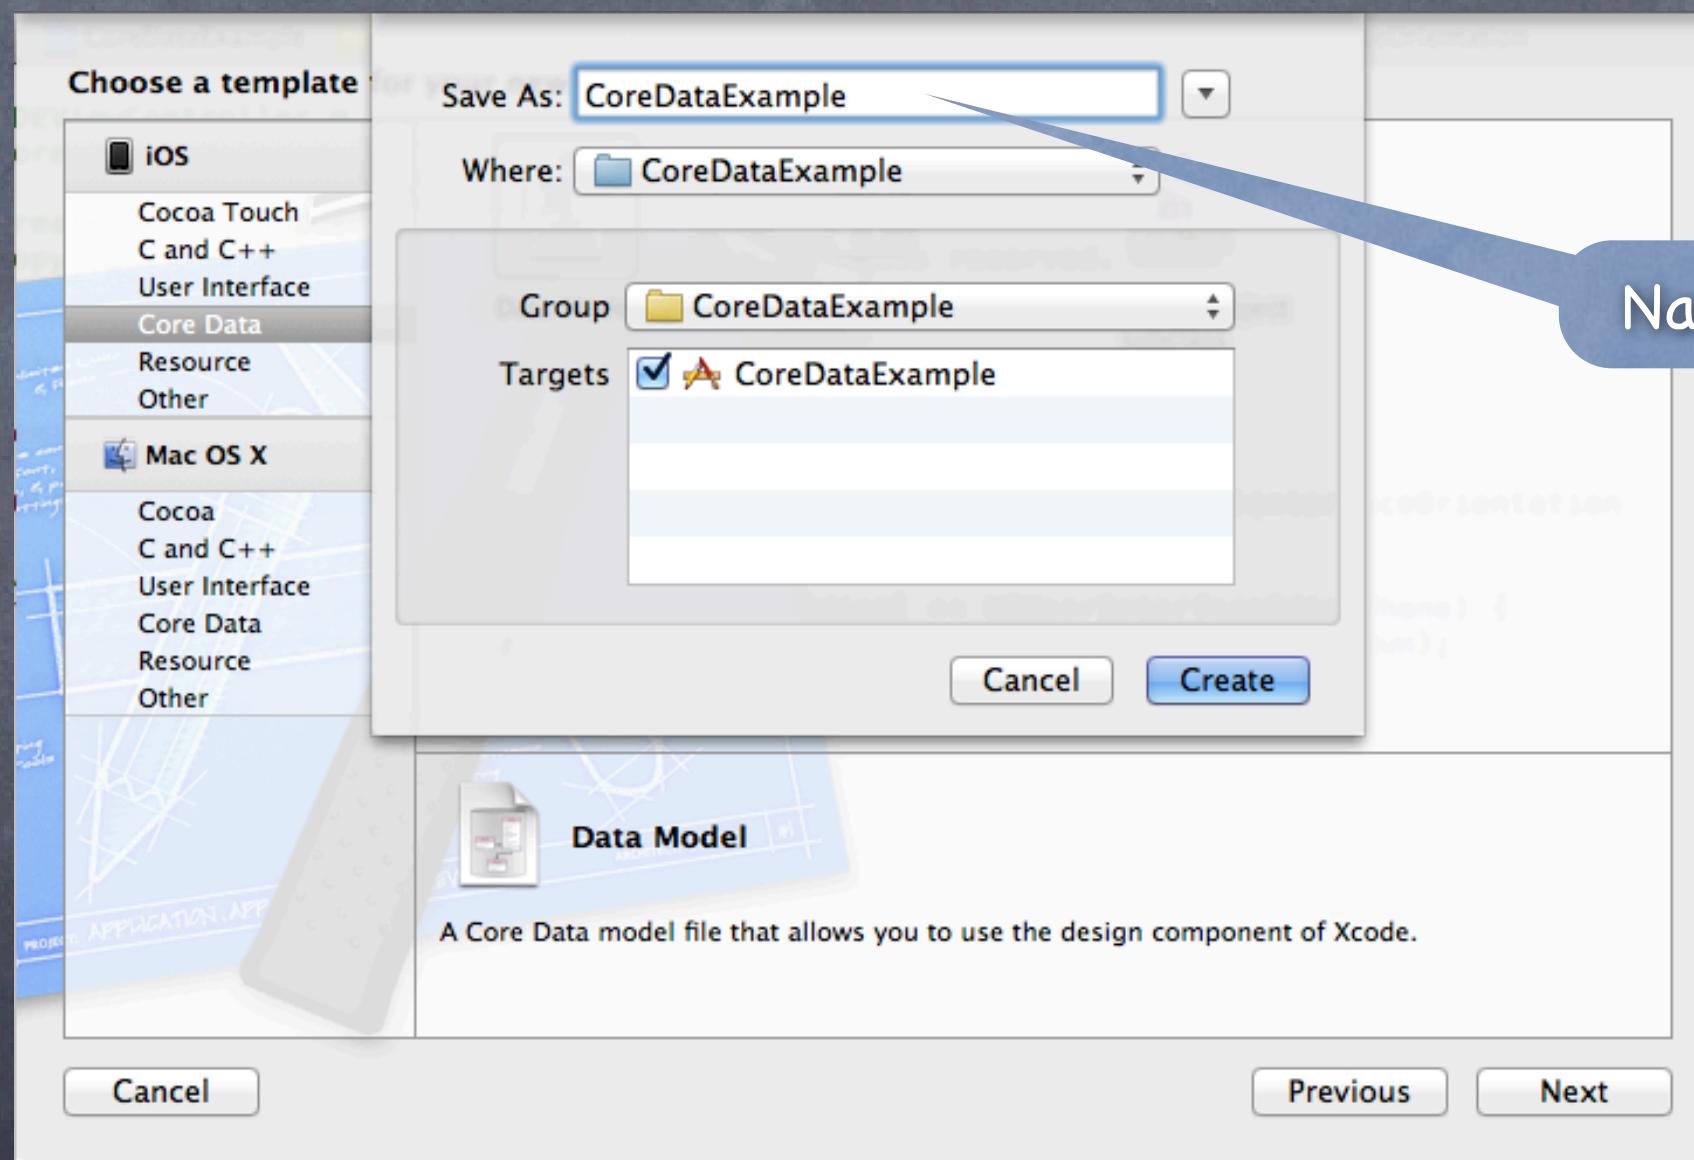

Core Data

- Creating a visual map of your application's database objects
New File ... then Data Model under Core Data.

Core Data

- Creating a visual map of your application's database objects
Unless we have multiple databases, usually we name the Data Model our application name

CoreDataExample > iOS Device Xcode

Set the type of the title Attribute.
All Attributes are objects.
Numeric ones are NSNumber.
Boolean is also NSNumber.
Binary Data is NSData.
Date is NSDate.
String is NSString.
Don't worry about Transformable.

Attributes are accessed on our NSManagedObject's via the methods valueForKey: and setValueForKey:. Or, if we subclass NSManagedObject, we can access Attributes as @property's.

Stanford CS193p Fall 2011

The screenshot shows the Xcode Core Data Model Editor. In the left sidebar, under 'ENTITIES', 'Photographer' is selected. A large blue callout points to this selection with the text 'Add another Entity.' and 'And set its name.' A second blue callout points to the 'Photographer' entity itself with the text 'A graphical version will appear.' A third blue callout points to the entity's attributes with the text 'These can be dragged around and positioned around the center of the graph.' A fourth blue callout points to the 'Photo' entity's attributes with the text 'Attributes can be added in the Graphic Editor too.' The right panel displays the 'Entity' configuration for 'Photographer', including its name, class (NSManagedObject), and other properties like indexes and versioning.

Here we add an Attribute called name to Photographer.

We can edit the attribute directly by double-clicking on it or the Inspector if we prefer.

Let's set its type as well.

Core Data

- ⦿ There are lots of other things you can do
But we are going to focus on creating Entities, Attributes and Relationships.
- ⦿ So how do you access all of this stuff in your code?
- ⦿ You need an **NSManagedObjectContext**
It is the hub around which all Core Data activity turns.
- ⦿ How do I get one?
There are two ways ...
 1. Create a **UIManagedDocument** and ask for its **managedObjectContext** (a @property).
 2. Click the “Use Core Data” button when you create a project.
(then your AppDelegate will have a **managedObjectContext** @property).We’re going to focus on doing the first one.

UIManagedDocument

• **UIManagedDocument**

It inherits from UIDocument which provides a lot of mechanism for the management of storage. If you use UIManagedDocument, you'll be on the fast-track to iCloud support. Think of a UIManagedDocument as simply a container for your Core Data database.

• **Creating a UIManagedDocument**

```
UIManagedDocument *document = [[UIManagedDocument] initWithFileURL:(URL *)url];
```

UIManagedDocument

- But you must open/create the document to use it

Check to see if it exists: `[[NSFileManager defaultManager] fileExistsAtPath:[url path]]`

If it does, open the document ...

`- (void)openWithCompletionHandler:(void (^)(BOOL success))completionHandler;`

If it does not, create it using ...

`- (void)saveToURL:(NSURL *)url
forSaveOperation:(UIDocumentSaveOperation)operation
completionHandler:(void (^)(BOOL success))completionHandler;`

- What is that completionHandler?

Just a **block** of code to execute when the open/save completes.

That's needed because the open/save is asynchronous!

Do not ignore this fact!

UIManagedDocument

Example

```
self.document = [[UIManagedDocument] initWithFileURL:(URL *)url];
if ([[NSFileManager defaultManager] fileExistsAtPath:[url path]]) {
    [document openWithCompletionHandler:^(BOOL success) {
        if (success) [self documentIsReady];
        if (!success) NSLog(@“couldn’t open document at %@”, url);
    }];
} else {
    [document saveToURL:url forSaveOperation:UIDocumentSaveForCreating
completionHandler:^(BOOL success) {
        if (success) [self documentIsReady];
        if (!success) NSLog(@“couldn’t create document at %@”, url);
    }];
}
// can't do anything with the document yet (do it in documentIsReady).
```

UIManagedDocument

- Once document is open/created, you can start using it

But you might want to check its `documentState` when you do ...

```
- (void)documentIsReady
{
    if (self.document.documentState == UIDocumentStateNormal) {
        NSManagedObjectContext *context = self.document.managedObjectContext;
        // do something with the Core Data context
    }
}
```

- Other `documentStates`

`UIDocumentStateClosed` (not opened or file does not exist yet)

`UIDocumentStateSavingError` (success will be NO)

`UIDocumentStateEditingDisabled` (temporarily unless failed to revert to saved)

`UIDocumentStateInConflict` (e.g., because some other device changed it via iCloud)

- The `documentState` is often “observed”

So it's about time we talked about using `NSNotification`s to observe other objects ...

NSNotification

• NSNotificationCenter

Get the default notification center via `[NSNotificationCenter defaultCenter]`

Then send it the following message if you want to observe another object:

```
- (void)addObserver:(id)observer      // you (the object to get notified)
              selector:(SEL)methodToSendIfSomethingHappens
              name:(NSString *)name // what you're observing (a constant somewhere)
              object:(id)sender;    // whose changes you're interested in (nil is anyone's)
```

• You will then be notified when the named event happens

```
- (void)methodToSendIfSomethingHappens:(NSNotification *)notification
{
    notification.name      // the name passed above
    notification.object    // the object sending you the notification
    notification.userInfo // notification-specific information about what happened
}
```

NSNotification

Example

```
NSNotificationCenter *center = [NSNotificationCenter defaultCenter];
```

Watching for changes in a document's state ...

```
[center addObserver:self  
    selector:@selector(documentChanged:  
        name:UIDocumentStateChangedNotification  
        object:self.document];
```

Don't forget to remove yourself when you're done watching.

```
[center removeObserver:self];
```

or

```
[center removeObserver:self name:UIDocumentStateChangedNotification object:self.document];
```

Failure to remove yourself can sometimes result in crashers.

This is because the NSNotificationCenter keeps an "unsafe unretained" pointer to you.

NSNotification

Another Example

Watching for changes in a CoreData database (made via a given NSManagedObjectContext) ...

```
- (void)viewDidAppear:(BOOL)animated
{
    [super viewDidAppear:animated];
    [center addObserver:self
                  selector:@selector(contextChanged:)
                  name:NSManagedObjectContextObjectsDidChangeNotification
                  object:self.document.managedObjectContext];
}
- (void)viewWillDisappear:(BOOL)animated
{
    [center removeObserver:self
                  name:NSManagedObjectContextObjectsDidChangeNotification
                  object:self.document.managedObjectContext];
    [super viewWillDisappear:animated];
}
```

There's also an NSManagedObjectContextDidSaveNotification.

NSNotification

- ⦿ **NSManagedObjectContextObjectsDidChangeNotification**

or **NSManagedObjectContextDidSaveNotification**

```
- (void)contextChanged:(NSNotification *)notification  
{
```

The `notification.userInfo` object is an `NSDictionary` with the following keys:

```
NSInsertedObjectsKey // an array of objects which were inserted  
NSUpdatedObjectsKey // an array of objects whose attributes changed  
NSDeletedObjectsKey // an array of objects which were deleted
```

```
}
```

- ⦿ **Other things to observe**

Look in the documentation for various classes in iOS.

They will document any notifications they will send out.

You can post your own notifications too (see `NSNotificationCenter` documentation).

Don't abuse this mechanism!

Don't use it to essentially get "global variables" in your application.

UIManagedDocument

- Okay, back to **UIManagedDocument** ...
- Saving a document (like creating or opening) is also asynchronous

Documents are auto-saved, but you can explicitly save as well.

You use the same method as when creating, but with a different "save operation."

```
[self.document saveToURL:self.document.fileURL  
    forSaveOperation:UIDocumentSaveForOverwriting  
    completionHandler:^(BOOL success) {  
        if (!success) NSLog(@"failed to save document %@", self.document.localizedDescription);  
    };  
    // the document is not saved at this point in the code (only once the block above executes)
```

Note the two **UIManagedDocument** properties used above:

```
@property (nonatomic, strong) NSURL *fileURL; // specified originally in initWithFileURL:  
@property (readonly) NSString *localizedName; // only valid once associated with a file
```

UIManagedDocument

- Closing a document is also asynchronous

The document will be closed if there are no strong pointers left to the UIManagedDocument.
But you can close it explicitly as well.

```
[self.document closeWithCompletionHandler:^(BOOL success) {  
    if (!success) NSLog(@"failed to close document %@", self.document.localizedDescription);  
};  
// the document is not closed at this point in the code (only once the block above executes)
```

UIManagedDocument

- Multiple instances of UIManagedDocument on the same document

This is perfectly legal, but understand that they will not share an NSManagedObjectContext.

Thus, changes in one will not automatically be reflected in the other.

You'll have to refetch in other UIManagedDocuments after you make a change in one.

Conflicting changes in two different UIManagedDocuments would have to be resolved by you!

It's exceedingly rare to have two "writing" instances of UIManagedDocument on the same file.

But a single writer and multiple readers? Not so rare. Just need to know when to refetch.

For your homework, we recommend not doing this

(i.e. we recommend only having one UIManagedDocument instance per actual document).

This will require you to have a bit of global API, but we'll forgive it this time :).

Hint #1 on the homework assignment will suggest an API to do this.

Core Data

- Okay, we have an **NSManagedObjectContext**, now what?

We grabbed it from an open **UIManagedDocument**'s **managedObjectContext** @property.

Now we use it to insert/delete objects in the database and query for objects in the database.

- Inserting objects into the database

```
NSManagedObject *photo =  
    [NSEntityDescription insertNewObjectForEntityForName:@"Photo"  
        inManagedObjectContext:(NSManagedObjectContext *)context];
```

Note that this **NSEntityDescription** class method returns an **NSManagedObject** instance.

All objects in the database are represented by **NSManagedObjects** or subclasses thereof.

An instance of **NSManagedObject** is a manifestation of an Entity in our Core Data model
(the model that we just graphically built in Xcode)

All the Attributes of a newly-inserted object will be nil
(unless you specify a default value in Xcode)

Core Data

- ⦿ How to access Attributes in an `NSManagedObject` instance

You can access them using the following two `NSKeyValueObserving` protocol methods ...

- `(id)valueForKey:(NSString *)key;`
- `(void)setValue:(id)value forKey:(NSString *)key;`

You can also use `valueForKeyPath:/setValue:forKeyPath:` and it will follow your relationships!

- ⦿ The key is an Attribute name in your data mapping

For example, @“thumbnailURL”

- ⦿ The value is whatever is stored (or to be stored) in the database

It'll be `nil` if nothing has been stored yet (unless Attribute has a default value in Xcode).

Note that all values are objects (numbers and booleans are `NSNumber` objects).

“To-many” mapped relationships are `NSSet` objects (or `NSOrderedSet` if ordered).

Non-“to-many” relationships are `NSManagedObjects`.

Binary data values are `NSData` objects.

Date values are `NSDate` objects.

Core Data

- Changes (writes) only happen in memory, until you save
 - Yes, `UIManagedDocument` auto-saves.
 - But explicitly saving when a batch of changes is made is good practice.

Core Data

- ⦿ But calling `valueForKey:/setValueForKey:` is pretty messy
 - There's no type-checking.
 - And you have a lot of literal strings in your code (e.g. `@“thumbnailURL”`)
- ⦿ What we really want is to set/get using `@propertys!`
- ⦿ No problem ... we just create a subclass of `NSManagedObject`
 - The subclass will have `@propertys` for each attribute in the database.
 - We name our subclass the same name as the Entity it matches (not strictly required, but do it).
 - And, as you might imagine, we can get Xcode to generate both the header file `@property` entries, and the corresponding implementation code (which is not `@synthesize`, so watch out!).

#import <CoreData/CoreData.h>  
  
@class Photo;  
  
@interface Photographer : NSManagedObject  
  
@property (nonatomic, retain) NSString * name;  
@property (nonatomic, retain) NSSet *photos;  
@end  
  
@interface Photographer (CoreDataGeneratedAccessors)  
  
- (void)addPhotosObject:(Photo *)value;  
- (void)removePhotosObject:(Photo *)value;  
- (void)addPhotos:(NSSet *)values;  
- (void)removePhotos:(NSSet *)values;  
@end
```

See? @propertys for all of Photographer's Attributes and Relationships.

These convenience methods are for putting Photo objects in and out of the photos Attribute.

But you can also just make a mutableCopy of the photos @property (creating an NSMutableSet), modify it, then put it back by setting the photos @property.

Add Entity Add Fetch Request Add Configuration

Add Attribute Add Fetched Property Add Relationship

Create NSManagedObject Subclass... Add Model Version... Import...

No Issues

Photo

- Attributes: photoURL, subtitle, thumbnailData, thumbnailURL, title, uploadDate
- Relationships: whoTook

Photographer

- Attributes: name
- Relationships: photos

Easy fix. Just generate the classes again.
Clearly there is an “order of generation” problem
(Photo was generated before Photographer was).

@implementation Photo

@dynamic photoURL;
@dynamic subtitle;
@dynamic thumbnailData;
@dynamic thumbnailURL;
@dynamic title;
@dynamic uploadDate;
@dynamic whoTook;

@end
```

Now let's look at Photo.m (the implementation).

What the heck is @dynamic?!

It says "I do not implement the setter or getter for this property, but send me the message anyway and I'll use the Objective-C runtime to figure out what to do."

There is a mechanism in the Objective-C runtime to "trap" a message sent to you that you don't implement.

NSManagedObject does this and calls valueForKey: or setValueForKey:. Pretty cool.

Core Data

- So how do I access my Entities' Attributes with dot notation?

```
Photo *photo = [NSEntityDescription insertNewObjectForEntityForName:@"Photo" inManagedObjectContext:...];  
NSString *myThumbnail = photo.thumbnailURL;  
photo.thumbnailData = [FlickrFetcher urlForPhoto:photoDictionary format:FlickrPhotoFormat...];  
photo.whoTook = ...; // a Photographer object we created or got by querying  
photo.whoTook.name = @"CS193p Instructor"; // yes, multiple dots will follow relationships
```

Core Data

- What if I want to add code to my NSManagedObject subclass?

Hmm, that's a problem.

Because you might want to modify your schema and re-generate the subclasses!

And it'd be really cool to be able to add code (very object-oriented).

Especially code to create an object and set it up properly (and also tear one down, it turns out).

Or maybe to derive new @propertys based on ones in the database
(e.g. a UIImage based on a URL in the database).

Time for an aside about an Objective-C feature called “categories” ...

Categories

- Categories are an Objective-C syntax for adding to a class ...
 - Without subclassing it.
 - Without even having to have access to the code of the class (e.g. its .m).

Examples

NSString's drawAtPoint:withFont: method.

This method is added by UIKit (since it's a UI method) even though NSString is in Foundation.

NSIndexPath's row and section properties (used in UITableView-related code)
are added by UIKit too, even though NSIndexPath is also in Foundation.

Syntax

```
@interface Photo (AddOn)  
- (UIImage *)image;  
@property (readonly) BOOL isOld;  
@end
```

Categories have their own .h and .m files (usually `ClassName+PurposeOfExtension.[mh]`).

Categories cannot have instance variables, so no `@synthesize` allowed in its implementation.

Categories

Implementation

```
@implementation Photo (AddOn)
- (UIImage *)image // image is not an attribute in the database, but photoURL is
{
    NSData *imageData = [NSData dataWithContentsOfURL:self.photoURL];
    return [UIImage imageWithData:imageData];
}
- (BOOL)isOld // whether this photo was uploaded more than a day ago
{
    return [self.uploadDate timeIntervalSinceNow] < -24*60*60;
}
@end
```

Other examples ... sometimes we add @propertys to an NSManagedObject subclass via categories to make accessing BOOL attributes (which are NSNumbers) cleaner.

Or we add @propertys to convert NSDatas to whatever the bits represent.

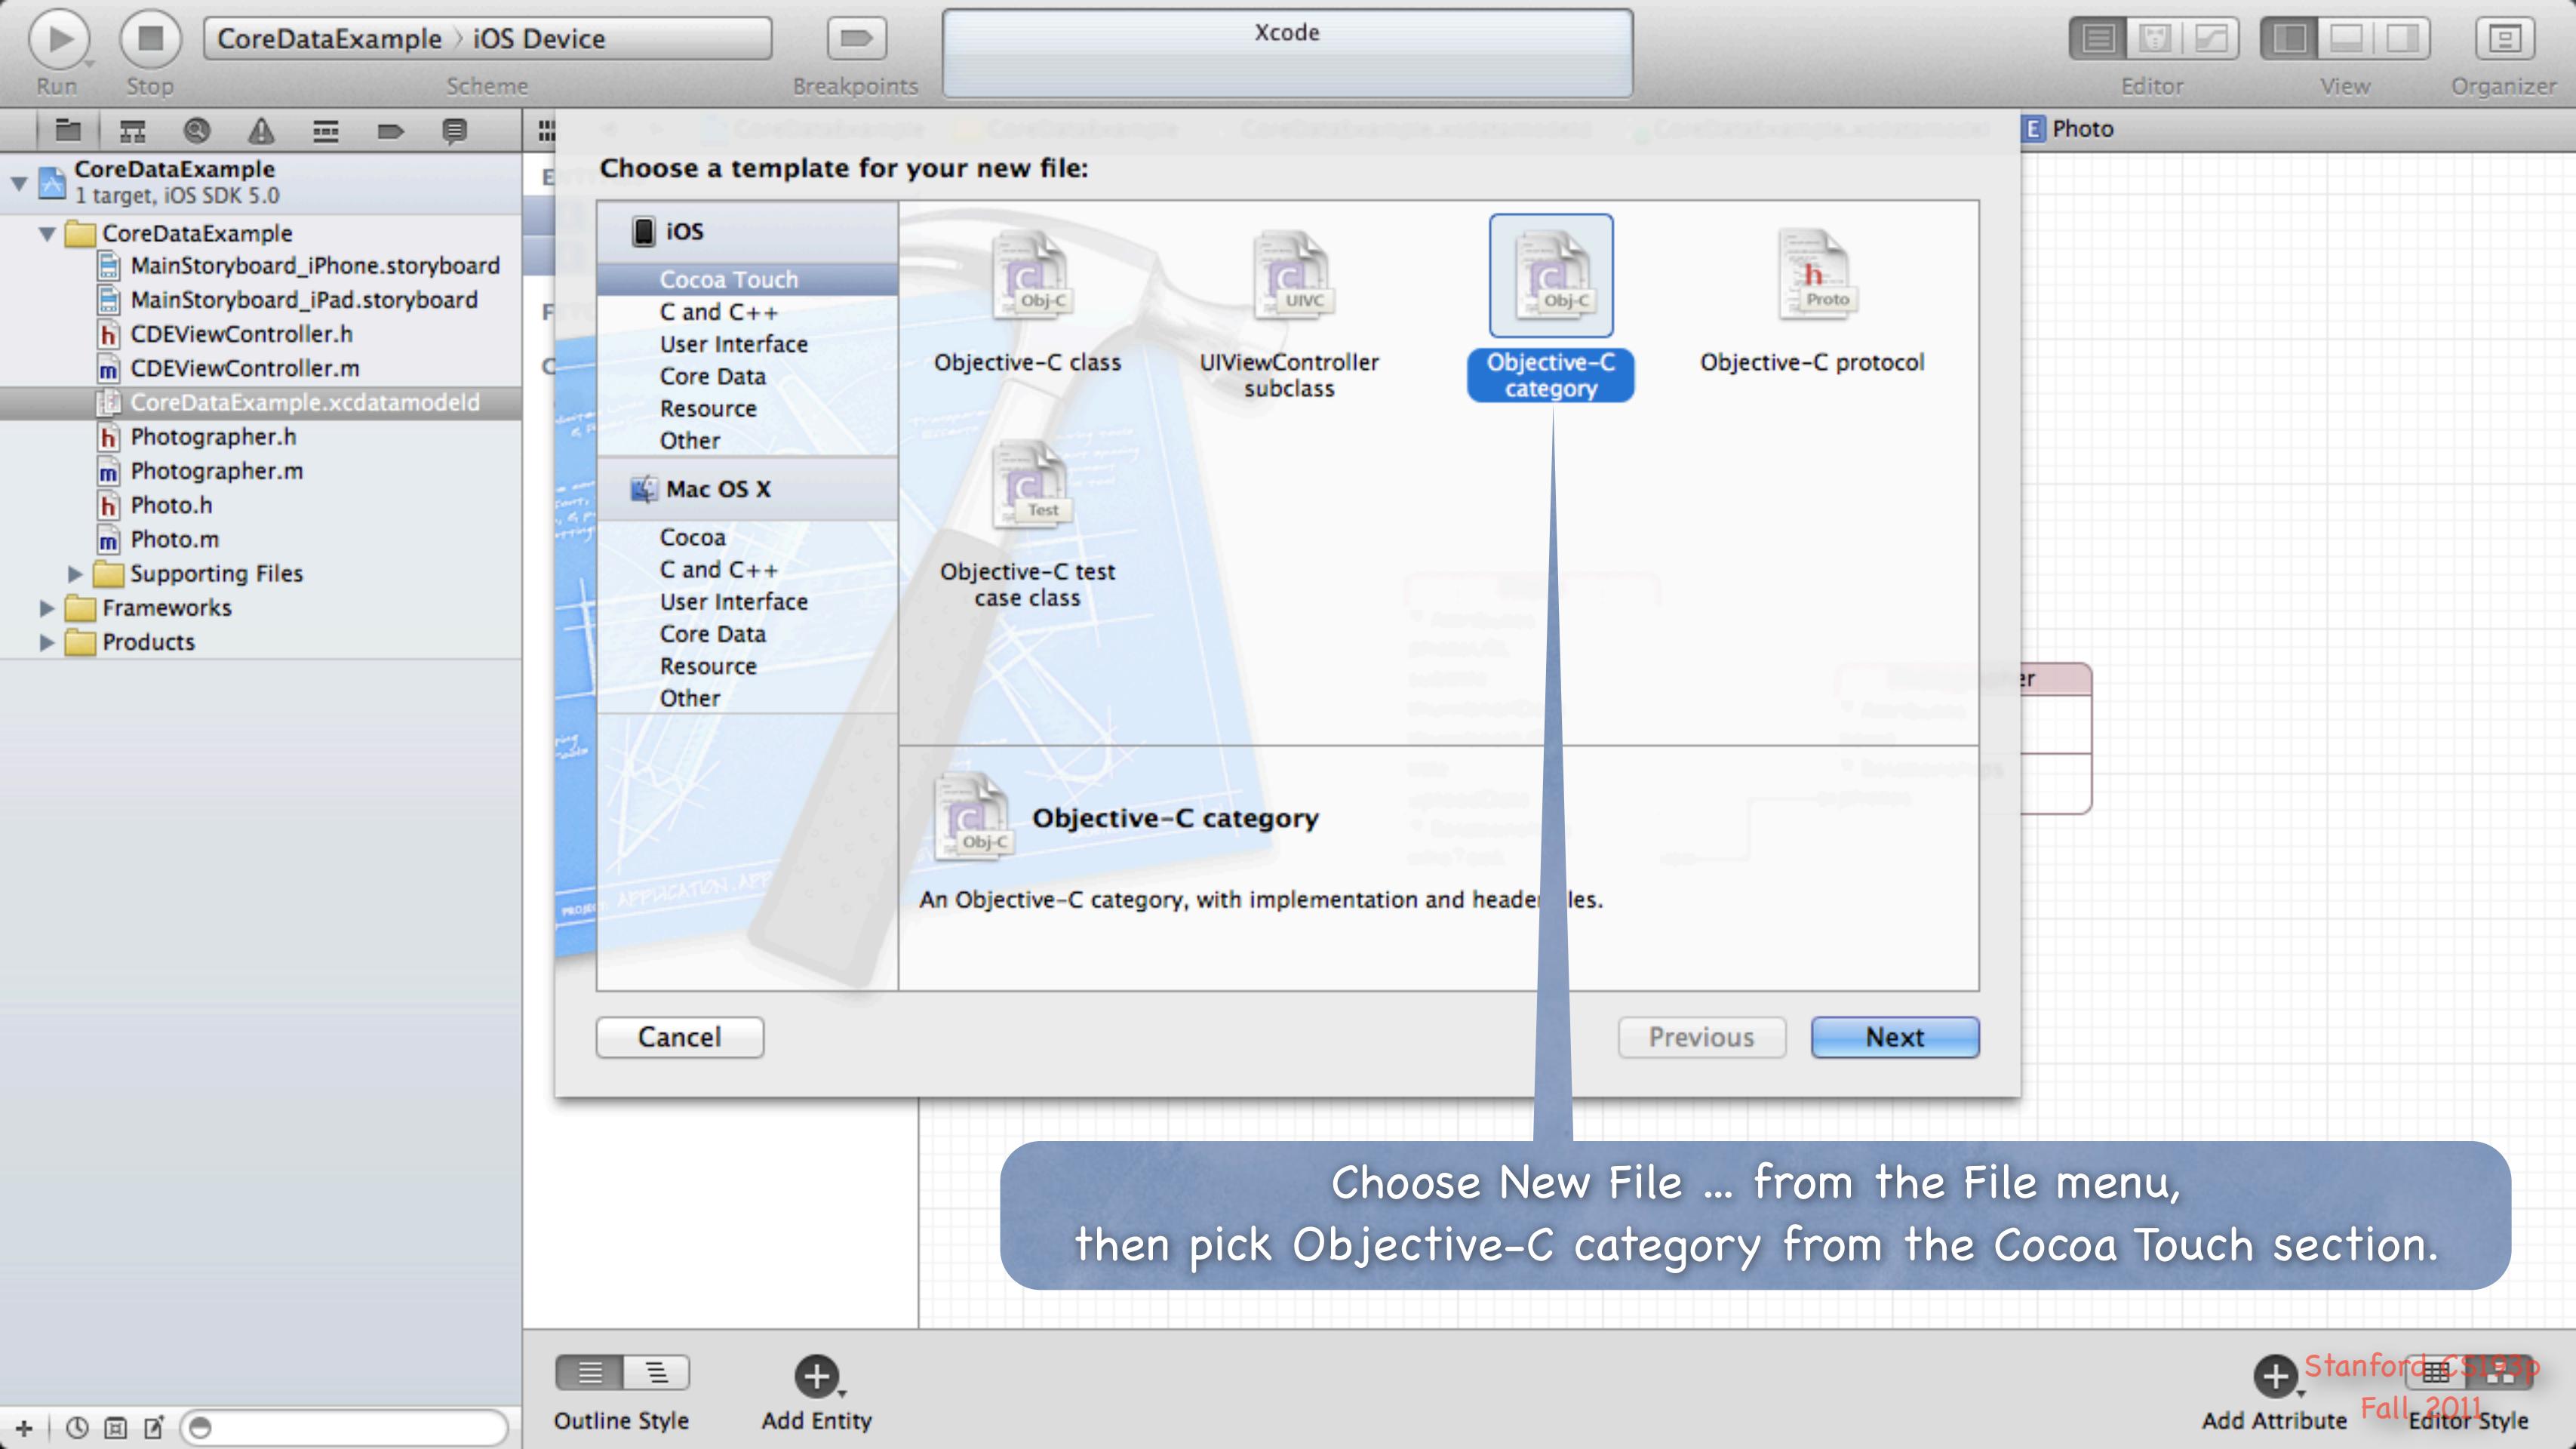

Any class can have a category added to it, but don't overuse/abuse this mechanism.

Categories

- Most common category on an NSManagedObject subclass?

Creation

```
@implementation Photo (Create)
+ (Photo *)photoWithFlickrData:(NSDictionary *)flickrData
    inManagedObjectContext:(NSManagedObjectContext *)context
{
    Photo *photo = ...; // see if a Photo for that Flickr data is already in the database
    if (!photo) {
        photo = [NSEntityDescription insertNewObjectForEntityForName:@"Photo"
                                             inManagedObjectContext:context];
        // initialize the photo from the Flickr data
        // perhaps even create other database objects (like the Photographer)
    }
    return photo;
}
@end
```

Choose New File ... from the File menu,
then pick Objective-C category from the Cocoa Touch section.

CoreDataExample > iOS Device Xcode Editor View Organizer

Run Stop Scheme Breakpoints

Choose options for your new file:

Category: Flickr

Category on: Photo

Cancel Previous Next

Enter the name of the category, as well as the name of the class the category's methods will be added to.

@end
```

Xcode will create both the .h and the .m for the category.
Remember, you cannot use @synthesize in this .m!

Stanford CS193p
Fall 2011

Deletion

• Deletion

Deleting objects from the database is easy (sometimes too easy!)

```
[self.document.managedObjectContext deleteObject:photo];
```

Make sure that the rest of your objects in the database are in a sensible state after this.

Relationships will be updated for you (if you set Delete Rule for relationship attributes properly).

And don't keep any strong pointers to photo after you delete it!

• `prepareForDeletion`

Here is another method we sometimes put in a category of an NSManagedObject subclass ...

```
@implementation Photo (Deletion)
```

```
- (void)prepareForDeletion
```

```
{
```

```
    // we don't need to set our whoTook to nil or anything here (that will happen automatically)
```

```
    // but if Photographer had, for example, a "number of photos taken" attribute,
```

```
    // we might adjust it down by one here (e.g. self.whoTook.photoCount--).
```

```
}
```

```
@end
```

Core Data

- ⦿ So far you can ...

Create objects in the database with `insertNewObjectForEntityForName:inManagedObjectContext:`.

Get/set properties with `valueForKey:/setValueForKey:` or `@property`s in a custom subclass.

Delete objects using the `NSManagedObjectContext deleteObject:` method.

- ⦿ One very important thing left to know how to do: QUERY

Basically you need to be able to retrieve objects from the database, not just create new ones

You do this by executing an `NSFetchRequest` in your `NSManagedObjectContext`

- ⦿ Four important things involved in creating an `NSFetchRequest`

1. Entity to fetch (required)
2. `NSPredicate` specifying which of those Entities to fetch (optional, default is all of them)
3. `NSSortDescriptors` to specify the order in which fetched objects are returned
4. How many objects to fetch at a time and/or maximum to fetch (optional, all)

Querying

• Creating an `NSFetchRequest`

We'll consider each of these lines of code one by one ...

```
NSFetchRequest *request = [NSFetchRequest fetchRequestWithEntityName:@"Photo"];
request.fetchBatchSize = 20;
request.fetchLimit = 100;
request.sortDescriptors = [NSArray arrayWithObject:sortDescriptor];
request.predicate = ...;
```

• Specifying the kind of Entity we want to fetch

A given fetch returns objects all of the same Entity.

You can't have a fetch that returns some Photos and some Photographers (one or the other).

• Setting fetch sizes/limits

If you created a fetch that would match 1000 objects, the request above faults 20 at a time.

And it would stop fetching after it had fetched 100 of the 1000.

Querying

• NSSortDescriptor

When we execute a fetch request, it's going to return an NSArray of NSManagedObjects. NSArray's are "ordered," so we have to specify the order when we fetch.

We do that by giving the fetch request a list of "sort descriptors" that describe what to sort by.

```
NSSortDescriptor *sortDescriptor =  
    [NSSortDescriptor sortDescriptorWithKey:@"thumbnailURL"  
                                    ascending:YES  
                                    selector:@selector(localizedCaseInsensitiveCompare:)];
```

There's another version with no selector: argument (default is the method compare:).

The selector: argument is just a method (conceptually) sent to each object to compare it to others.

Some of these "methods" might be smart (i.e. they can happen on the database side).

We give a list of these to the NSFetchedRequest because sometimes we want to sort first by one key (e.g. last name), then, within that sort, sort by another (e.g. first name).

Querying

• NSPredicate

This is the guts of how we specify exactly which objects we want from the database.

• Predicate formats

Creating one looks a lot like creating an `NSString`, but the contents have semantic meaning.

```
NSString *serverName = @“flickr-5”;  
NSPredicate *predicate =  
    [NSPredicate predicateWithFormat:@“thumbnailURL contains %@", serverName];
```

• Examples

```
@“uniqueId = %@", [flickrInfo objectForKey:@“id”] // unique a photo in the database  
@“name contains[c] %@", (NSString *) // matches name case insensitively  
@“viewed > %@", (NSDate *) // viewed is a Date attribute in the data mapping  
@“whoTook.name = %@", (NSString *) // Photo search (by photographer’s name)  
@“any photos.title contains %@", (NSString *) // Photographer search (not a Photo search)
```

Many more options. Look at the class documentation for `NSPredicate`.

Querying

• NSCompoundPredicate

You can use AND and OR inside a predicate string, e.g. @“(name = %@) OR (title = %@)”

Or you can combine NSPredicate objects with special NSCompoundPredicates.

```
NSArray *array = [NSArray arrayWithObjects:pred1, pred2, nil];
```

```
NSPredicate *pred = [NSCompoundPredicate andPredicateWithSubpredicates:array];
```

This predicate is “pred1 AND pred2”.

“Or” predicate also available, of course.

Querying

Putting it all together

Let's say we want to query for all Photographers ...

```
NSFetchRequest *request = [NSFetchRequest fetchRequestWithEntityName:@"Photographer"];
```

... who have taken a photo in the last 24 hours ...

```
NSDate *yesterday = [NSDate dateWithTimeIntervalSinceNow:-24*60*60];
```

```
request.predicate = [NSPredicate predicateWithFormat:@"any photos.uploadDate > %@", yesterday];
```

... sorted by the Photographer's name ...

```
NSSortDescriptor *sortByName = [NSSortDescriptor sortDescriptorWithKey:@"name" ascending:YES];
```

```
request.sortDescriptors = [NSArray arrayWithObject:sortByName];
```

Executing the fetch

```
NSManagedObjectContext *moc = self.document.managedObjectContext;
```

```
NSError *error;
```

```
NSArray *photographers = [moc executeFetchRequest:request error:&error];
```

Returns `nil` if there is an error (check the `NSError` for details).

Returns an empty array (not `nil`) if there are no matches in the database.

Returns an array of `NSManagedObjects` (or subclasses thereof) if there were any matches.

You can pass `NULL` for `error:` if you don't care why it fails.

Querying

• Faulting

The above fetch does not necessarily fetch any actual data.

It could be an array of “as yet unfaulted” objects, waiting for you to access their attributes.

Core Data is very smart about “faulting” the data in as it is actually accessed.

For example, if you did something like this ...

```
for (Photographer *photographer in photographers) {  
    NSLog(@"fetched photographer %@", photographer);  
}
```

You may or may not see the names of the photographers in the output
(you might just see “unfaulted object”, depending on whether it prefetched them)

But if you did this ...

```
for (Photographer *photographer in photographers) {  
    NSLog(@"fetched photographer named %@", photographer.name);  
}
```

... then you would definitely fault all the Photographers in from the database.

Core Data

- There is so much more (that we don't have time to talk about)!
 - Optimistic locking (`deleteConflictsForObject:`)
 - Rolling back unsaved changes
 - Undo/Redo
 - Staleness (how long after a fetch until a refetch of an object is required?)

Coming Up

- ⦿ Thursday

More Core Data
